Output synchronization of unknown heterogeneous agents via distributed model reference adaptation

Simone Baldi, *Member, IEEE*, Shuai Yuan and Paolo Frasca, *Member, IEEE*

Abstract—This work presents a distributed model reference adaptive methodology for output synchronization of heterogeneous linear agents with unknown dynamics. We consider a setting in which the control input is communicated among neighbors, instead of observer variables. For those agents that can access the signals of the reference model, classical model reference adaptation laws lead to leader synchronization; for those agents that cannot access such signals, synchronization must be achieved by taking the neighboring agents as an alternative reference model. We show that these two groups of agents give rise to two types of matching conditions: the standard conditions to match the reference model, and new distributed matching conditions among neighboring agents. Since all matching gains are unknown, the gains are adapted online via Lyapunov-based estimation. Asymptotic synchronization is proven analytically, and numerical examples show the effectiveness of the approach.

Index Terms—Output synchronization, distributed adaptive control, heterogeneous unknown agents.

I. INTRODUCTION

IN recent years, cooperative control of multiagent systems has received the attention of many scientific communities, due to its impact in formation flying, smart energy, smart traffic and other crucial areas [1]–[5]. An important problem in cooperative control is to achieve in a distributed way (i.e. using local information) a common behavior for the entire network: this is the so-called synchronization problem [6], [7], sometimes referred to as the consensus problem [8]–[11] when the behavior to be achieved is a constant. Synchronization serves as a building block for more sophisticated coordination tasks [12]: popular forms of synchronization are based on creating homogeneous dynamics (homogenization), e.g. by endowing all agents with an internal model of the common behavior to be achieved [13], [14], or by matching some desired dynamics [15], [16]. In literature we can distinguish at least two families of protocols through which synchronization can be implemented. In the first family, the agents that are not connected to the leader generating the reference signal will construct an observation of such signal via a *distributed observer* [13], [17]. In the second family, a *distributed input* is used in place of the distributed observer: in other words, communication of the control input is adopted in place of communicating the observer variables [18]–[20]. Advances in the distributed input approach include stability of the interconnected system

[21], or addressing the presence of switching communication topologies [22]. Variants to this strategy include discontinuous strategies based on sliding mode [23], [24].

Synchronizing solutions have been proposed when the agents are uncertain but homogeneous [25], [26], heterogeneous with no uncertainty [27], [28], or heterogeneous with specific structural uncertainty [29]. Despite these results, synchronization in the joint presence of heterogeneity and uncertainty is still a major problem. Using the homogenization framework, the idea is to cancel the effects of heterogeneity and/or uncertainty via feedback gains: up to now, non-adaptive (i.e. fixed-gain) feedback with possibly adaptive coupling weights has been mainly explored [30]–[32]. However, it is well known that as uncertainty grows bigger and bigger no fixed-gain feedback may cope with it [33]. Therefore, it is of fundamental importance to integrate adaptive control methodologies in cooperative control, so that teams of agents can respond to parametric changes that might occur while the cooperative task is carried out. Output synchronization in the joint presence of heterogeneity and uncertainty has been proposed, with distributed observer protocols, for the special class of Euler-Lagrange agents [34], [35]: however, no adaptive output synchronization protocols have been reported using distributed input protocols, which motivates this work.

The main contribution of this work is an adaptive methodology based on distributed input protocol for output synchronization of heterogeneous agents with linear and unknown dynamics. A distributed model reference adaptive control framework is used to solve the problem. For the agents with direct access to the leader signals, the classical reference model idea is adopted; for the agents with access to the leader signals a new reference model is defined by the neighboring agents to which each agent aims to converge. Homogenization of the two groups of agents gives rise to two types of matching conditions: the classical matching conditions between an agent and the reference model, and new distributed matching conditions among neighboring agents. Since all matching gains are unknown (in view of the unknown dynamics), we design a Lyapunov-based adaptation to handle possibly large uncertainties. Asymptotic synchronization error is shown analytically on acyclic graphs, and extensions to general graphs are discussed both analytically and via numerical examples.

The paper is organized as follows: Sect. II formulates the problem and Sect. III recalls the standard matching conditions for model reference synchronization. Sect. IV introduces the new distributed matching conditions for those agents not connected to the reference model. Sect. V contains the main synchronization, Sect. VI demonstrates the findings via simulations and Sect. VII concludes the work.

Grenoble Alpes), GIPSA-Lab, France. E-mails: s.baldi@tudelft.nl, s.yuan-1@tudelft.nl, paolo.frasca@gipsa-lab.fr. The work has been partially funded by EC, FP7-ICT-2013.3.4, under contract #611538 (LOCAL4GLOBAL)

Notation: The transpose and Euclidean norm of a (column) vector are indicated with x^T and $\|x\|$, respectively. A signal $x: \mathbb{R} \rightarrow \mathbb{R}^n$ belongs to \mathcal{L}_2 class ($x \in \mathcal{L}_2$) if $\int_0^t \|x(\tau)\|^2 d\tau < \infty$, $\forall t \geq 0$, and to \mathcal{L}_∞ class ($x \in \mathcal{L}_\infty$), if $\max_{t \geq 0} \|x(t)\| < \infty$, $\forall t \geq 0$.

A directed graph (digraph) is indicated with the pair $(\mathcal{N}, \mathcal{E})$, where \mathcal{N} is a finite set of nodes, and $\mathcal{E} \in \mathcal{N} \times \mathcal{N}$ is a set of ordered pair of nodes, called edges. The adjacency matrix $\mathcal{A} = [a_{ij}]$ of a weighted digraph is defined as $a_{ii} = 0$ and $a_{ij} > 0$ if $(j, i) \in \mathcal{E}$, where $i \neq j$, while the Laplacian matrix is defined as $\mathcal{L} = [l_{ij}]$, where $l_{ii} = \sum_j a_{ij}$ and $l_{ij} = -a_{ij}$, if $i \neq j$.

II. PROBLEM FORMULATION

For ease of presentation, let us start by formulating a simple synchronization problem for two agents, denoted with subscripts 1 and 2. Omitting the time index t for brevity, their dynamics are expressed in the transfer function¹ form

$$\begin{aligned} y_1 &= G_1(s)u_1 = k_1 \frac{Z_1(s)}{R_1(s)} u_1 \\ y_2 &= G_2(s)u_2 = k_2 \frac{Z_2(s)}{R_2(s)} u_2 \end{aligned} \quad (1)$$

where $u_1, u_2 \in \mathbb{R}$ and $y_1, y_2 \in \mathbb{R}$ are the inputs and the outputs of the two agents; the polynomials $Z_1(s)$, $Z_2(s)$ and $R_1(s)$, $R_2(s)$ are *unknown* monic polynomials and k_1, k_2 are *unknown* constants referred to as the high frequency gains.

Let us assume a directed connection from agent 1 to agent 2, i.e. the corresponding digraph is described by $\mathcal{N} = \{1, 2\}$, $\mathcal{E} = \{(1, 2)\}$. Let us also introduce the connection of agent 1 to a reference model (leader) denoted with the subscript 0

$$y_0 = G_0(s)r = k_0 \frac{Z_0(s)}{R_0(s)} r \quad (2)$$

where $r \in \mathbb{R}$, $y_0 \in \mathbb{R}$ are the reference and the output of the reference model. The polynomials $Z_0(s)$, $R_0(s)$ are *known* monic polynomials and k_0 is the *known* high frequency gain. As agent 1 is the only agent that can access the reference input r , let us consider the following problem:

Synchronization to the reference model for two agents: Find a distributed synchronization protocol that achieves, for any bounded r and using only local measurements, the following tasks: for agent 1, synchronize to the output of the reference model, i.e. $y_1 \rightarrow y_0$ for $t \rightarrow \infty$; for agent 2 (which cannot synchronize to agent 0 directly) synchronize to the output of agent 1, i.e. $y_2 \rightarrow y_1$ for $t \rightarrow \infty$, which implies $y_2 \rightarrow y_0$.

To meet the synchronization objectives, we need some well-posedness assumptions, classical in adaptive control [37].

Agent assumptions:

- A1.** $Z_i(s)$, $i \in \{1, 2\}$, are monic Hurwitz polynomials;
- A2.** An upper bound n to the degree n_i of $R_i(s)$, $i \in \{1, 2\}$, is known;
- A3.** The relative degree $n^* = n_i - m_i$ of $G_i(s)$, $i \in \{1, 2\}$, is known, where m_i is the degree of the numerator $Z_i(s)$;
- A4.** The signs of the high frequency gains k_i , $i \in \{1, 2\}$, are known.

¹We consider the single-input single-output case: multivariable extension is possible via appropriate canonical forms [36], which are not considered here to avoid technicalities that might hide the key ideas behind the approach.

Reference model assumptions:

M1. $Z_0(s)$, $R_0(s)$ are monic Hurwitz polynomials;

M2. The relative degree of $G_0(s)$ is also n^* .

Assumption for ease of presentation:

E1. The relative degree is $n^* = 1$ and $G_0(s)$ is strictly positive real² (SPR).

Remark 1. Assumptions A1-A4 and M1-M2 stem from the model reference adaptive control framework used to achieve synchronization [37]. Assumption A1 requires the agents to be minimum phase, while M1 obviously imposes the reference model to be open-loop stable. Assumptions A2, A3 and M2 are required to define the degree of the control law, while A4 determines the sign of the adaptation law. Assumption E1 gives a straightforward Lyapunov analysis which makes the presentation of the design easier: extensions to $n^* > 1$ and non strictly positive real $G_0(s)$ can be obtained as discussed in [38, Sect. 6.4.2 and 6.4.3].

III. HOMOGENIZATION VIA MATCHING CONDITIONS

If an agent j can access the reference input r , synchronization among agents 0 and j is known in literature as model reference adaptive control [37]: the approach (here briefly recalled) passes through a control law in the form

$$a_{0j}u_j = a_{0j}l_j^* \frac{\alpha(s)}{\Lambda(s)} u_j + a_{0j}f_j^* \frac{\alpha(s)}{\Lambda(s)} y_j + a_{0j}g_j^* y_j + a_{0j}c_j^* r \quad (3)$$

where a_{0j} is the weighted connection between agents j and 0 (the term a_{0j} in (3) has not been simplified in order to be consistent with the next sections where multiple connections with other agents might be present). In (3), $\Lambda(s)$ is a Hurwitz monic polynomial to be designed as $\Lambda(s) = \Lambda_0(s)Z_0(s)$, with $\Lambda_0(s)$ Hurwitz: $\alpha(s)$ is a vector defined as

$$\begin{aligned} \alpha(s) &= [s^{n-2} \quad s^{n-3} \quad \dots \quad s \quad 1]^T \quad \text{for } n \geq 2 \\ \alpha(s) &= 0 \quad \text{for } n = 1. \end{aligned} \quad (4)$$

The next step is to find the conditions under which a control law in the form (3) makes agent j to match the reference model (2), i.e. to have its same transfer function

$$\frac{y_j(s)}{r(s)} = k_0 \frac{Z_0(s)}{R_0(s)}. \quad (5)$$

Such conditions are obtained by writing y_j in closed loop

$$\begin{aligned} y_j &= k_j \frac{Z_j(s)}{R_j(s)} \left(l_j^* \frac{\alpha(s)}{\Lambda(s)} u_j + f_j^* \frac{\alpha(s)}{\Lambda(s)} y_j + g_j^* y_j + c_j^* r \right) \\ \frac{y_j(s)}{r(s)} &= \frac{\frac{c_j^* k_j Z_j(s)}{R_j(s)}}{\left(1 - \frac{l_j^* \alpha(s)}{\Lambda(s)} - \frac{f_j^* \alpha(s)}{\Lambda(s)} \frac{k_j Z_j(s)}{R_j(s)} - g_j^* \frac{k_j Z_j(s)}{R_j(s)} \right)}. \end{aligned} \quad (6)$$

By comparing the transfer functions (2) and (6) we derive the matching conditions between agent j and the reference model:

$$\begin{aligned} R_j(s)(\Lambda(s) - l_j^* \alpha(s)) - k_j Z_j(s)(f_j^* \alpha(s) + g_j^* \Lambda(s)) \\ = Z_j(s)R_0(s)\Lambda_0(s) \end{aligned} \quad (7)$$

²A strictly positive-real rational function $G(s)$ is real when s is real and has strictly positive real part when s has a strictly positive real part.

and $c_j^* = k_0/k_j$. The matching condition (7) and control law (3) present two problems: the first one is that solution of (7) requires the knowledge of the polynomials $Z_j(s)$, $R_j(s)$ and of the constants k_j , which are all unknown. The second problem is that, even if all parameters were perfectly known, (3) can be implemented only by the agents with access to r . In the rest of this section we see how to overcome the first problem, while in Section IV we address the second problem.

With reference to our network with two agents 1 and 2, as the gains l_1^* , f_1^* , g_1^* , and c_1^* for the controller (3) of agent 1 are unknown, let us use

$$a_{01}u_1 = a_{01}l_1^T \frac{\alpha(s)}{\Lambda(s)} u_1 + a_{01}f_1^T \frac{\alpha(s)}{\Lambda(s)} y_1 + a_{01}g_1 y_1 + a_{01}c_1 r \quad (8)$$

where l_1 , f_1 , g_1 , and c_1 are estimates for l_1^* , f_1^* , g_1^* , and c_1^* respectively, derived via the following well-known adaptive control result.

Result 1. [37] Under Assumptions A1-A4, M1-M2 and E1, the following adaptive law

$$\begin{aligned} \dot{\omega}_{u_1} &= F\omega_{u_1} + du_1 & \dot{\omega}_{y_1} &= F\omega_{y_1} + dy_1 \\ a_{01}u_1 &= \theta_1^T \omega_1 \\ \dot{\theta}_1 &= -\Gamma a_{01}e_{10}\omega_1 \text{sgn}\left(\frac{k_1}{k_0}\right) \end{aligned} \quad (9)$$

where $e_{10} = y_1 - y_0$, $\Gamma > 0$ and

$$\omega_1 = \begin{bmatrix} a_{01}\omega_{u_1} \\ a_{01}\omega_{y_1} \\ a_{01}y_1 \\ a_{01}r \end{bmatrix}, \quad F = \begin{bmatrix} -\lambda_{n-2} & \dots & -\lambda_0 \\ I_{n-2} & & 0 \end{bmatrix}, \quad d = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \quad (10)$$

and λ_i are the coefficient of

$$\Lambda(s) = s^{n-1} + \lambda_{n-2}s^{n-2} + \dots + \lambda_1 s + \lambda_0 \quad (11)$$

guarantees $y_1 \rightarrow y_0$ for $t \rightarrow \infty$

Proof. A sketch of the proof is recalled, which will be useful to understand the main synchronization result. Since (F, d) is a state-space realization of $\frac{\alpha(s)}{\Lambda(s)}$, the adaptive law (9) is a state-space realization of controller (8) with

$$\theta_1 = [l_1^T \quad f_1^T \quad g_1 \quad c_1]^T. \quad (12)$$

Let us take an analogous state-space realization of the ideal control law (3)

$$a_{01}u_1^* = \theta_1^{*T} \omega_1 \quad (13)$$

where $\theta_1^* = [l_1^{*T} \quad f_1^{*T} \quad g_1^* \quad c_1^*]^T$. Adopting a state-space realization of agent 1

$$\begin{aligned} \dot{x}_1 &= A_1 x_1 + b_1 u_1 \\ y_1 &= h_1^T x_1 \end{aligned} \quad (14)$$

and after augmenting the state x_1 with the controller states, $\bar{x}_1 = [x_1^T \quad \omega_{u_1}^T \quad \omega_{y_1}^T]^T$, we obtain

$$\begin{aligned} \dot{\bar{x}}_1 &= \bar{A}_1 \bar{x}_1 + \bar{B}_1 c_1^* r + \bar{B}_1 (u_1 - \theta_1^{*T} \bar{\omega}_1) \\ y_1 &= \bar{C}_1^T \bar{x}_1 \end{aligned} \quad (15)$$

with $\bar{\omega}_1 = \omega_1/a_{01}$ and

$$\begin{aligned} \bar{A}_1 &= \begin{bmatrix} A_1 + b_1 g_1^* h_1^T & b_1 l_1^{*T} & b_1 f_1^{*T} \\ d g_1^* h_1^T & F + d l_1^{*T} & d f_1^{*T} \\ d h_1^T & 0 & F \end{bmatrix}, \\ \bar{B}_1 &= \begin{bmatrix} b_1 \\ d \\ 0 \end{bmatrix}, \quad \bar{C}_1^T = [h_1^T \quad 0 \quad 0]. \end{aligned} \quad (16)$$

Let us now take the following non-nominal state-space representation of the reference model

$$\begin{aligned} \dot{\bar{x}}_0 &= \bar{A}_1 \bar{x}_0 + \bar{B}_1 c_1^* r \\ y_0 &= \bar{C}_1^T \bar{x}_0. \end{aligned} \quad (17)$$

After defining $\tilde{x}_{10} = \bar{x}_1 - \bar{x}_0$, we obtain the error dynamics

$$\begin{aligned} \dot{\tilde{x}}_{10} &= \bar{A}_1 \tilde{x}_{10} + \bar{B}_1 (u_1 - \theta_1^{*T} \bar{\omega}_1) \\ e_{10} &= \bar{C}_1^T \tilde{x}_{10} \end{aligned} \quad (18)$$

which become, after substituting (8) into the (18)

$$\begin{aligned} \dot{\tilde{x}}_{10} &= \bar{A}_1 \tilde{x}_{10} + \bar{\bar{B}}_1 \rho_1^* \tilde{\theta}_1^T \bar{\omega}_1 \\ e_{10} &= \bar{C}_1^T \tilde{x}_{10} \end{aligned} \quad (19)$$

where $\bar{\bar{B}}_1 = \bar{B}_1 c_1^*$, $\rho_1^* = \frac{1}{c_1^*}$, and $\tilde{\theta}_1 = \theta_1 - \theta_1^*$. In addition, it can be verified that [38, Sect. 6.3.2, eq. (6.3.25)]

$$\bar{C}_1 (sI - \bar{A}_1)^{-1} \bar{\bar{B}}_1 = G_0(s). \quad (20)$$

As $G_0(s)$ is taken to be strictly positive-real from E1, we can consider the Lyapunov function

$$V_1(\tilde{\theta}_1, \tilde{x}_{10}) = a_{01}^2 \frac{\tilde{x}_{10}^T P \tilde{x}_{10}}{2} + \frac{\tilde{\theta}_1^T \Gamma^{-1} \tilde{\theta}_1}{2} |\rho_1^*| \quad (21)$$

where $P = P^T > 0$ satisfies the Kalman-Yakubovich Lemma

$$\begin{aligned} P \bar{A}_1 + \bar{A}_1^T P &= -qq^T - \nu L \\ P \bar{\bar{B}}_1 &= \bar{C}_1 \end{aligned} \quad (22)$$

with $L = L^T > 0$, and $\nu > 0$. The time derivative of V_1 is

$$\begin{aligned} \dot{V}_1 &= -a_{01}^2 \frac{\tilde{x}_{10}^T q q^T \tilde{x}_{10}}{2} - a_{01}^2 \frac{\nu}{2} \tilde{x}_{10}^T L \tilde{x}_{10} \\ &\quad + a_{01} \tilde{x}_{10}^T P \bar{\bar{B}}_1 \rho_1^* \tilde{\theta}_1^T \bar{\omega}_1 + \tilde{\theta}_1^T \Gamma^{-1} \dot{\tilde{\theta}}_1 |\rho_1^*| \end{aligned} \quad (23)$$

since $\tilde{x}_{10}^T P \bar{\bar{B}}_1 = \tilde{x}_{10}^T \bar{C}_1 = e_{10}$ and $\rho_1^* = |\rho_1^*| \text{sgn}(\rho_1^*)$, we can delete the last two terms by choosing

$$\dot{\tilde{\theta}}_1 = \dot{\theta}_1 = -\Gamma a_{01} e_{10} \omega_1 \text{sgn}(\rho_1^*) \quad (24)$$

which leads to

$$\dot{V}_1 = -a_{01}^2 \frac{\tilde{x}_{10}^T q q^T \tilde{x}_{10}}{2} - a_{01}^2 \frac{\nu}{2} \tilde{x}_{10}^T L \tilde{x}_{10}. \quad (25)$$

From (25) we obtain that V_1 has a finite limit, and therefore $\tilde{x}_{10}, \tilde{\theta}_1 \in \mathcal{L}_\infty$. Because $\tilde{x}_{10} = \bar{x}_1 - \bar{x}_0 \in \mathcal{L}_\infty$ and $\bar{x}_0 \in \mathcal{L}_\infty$, we have $\bar{x}_1 \in \mathcal{L}_\infty$. This implies $x_1, y_1, \omega_1 \in \mathcal{L}_\infty$. Since from (25) we can establish that \dot{V}_1 has bounded integral, we have $\tilde{x}_{10}, e_{10} \in \mathcal{L}_2$. Furthermore using $\theta_1, \omega_1, \tilde{x}_{10} \in \mathcal{L}_\infty$ in (19) we have $e_{10}, \dot{e}_{10} \in \mathcal{L}_\infty$. From Barbalat's Lemma, this implies $e_{10} \rightarrow 0$ for $t \rightarrow \infty$, which concludes the proof. \square

IV. DISTRIBUTED MATCHING CONDITIONS

The control law (8) with adaptation (9) removes the problem of unknown $l_{ji}^*, f_{ji}^*, g_{ji}^*$ and c_{ji}^* : yet, a problem remains as the control law (8) is implementable only for those agents with access to r . To overcome this problem, we will derive new (distributed) matching conditions between neighboring agents j and i . The following proposition is given.

Proposition 1. Let us consider an agent j not connect to the reference model. For a control law in the form

$$\begin{aligned} \sum_{i=1}^N a_{ij} u_j = & \sum_{i=1}^N a_{ij} l_{ji}^{*T} \frac{\alpha(s)}{\Lambda(s)} u_i + \sum_{i=1}^N a_{ij} f_{ji}^{*T} \frac{\alpha(s)}{\Lambda(s)} y_i + \sum_{i=1}^N a_{ij} g_{ji}^* y_i \\ & + \sum_{i=1}^N a_{ij} c_{ji}^* u_i + l_j^{*T} \frac{\alpha(s)}{\Lambda(s)} \sum_{i=1}^N a_{ij} (u_j - u_i) \\ & + f_j^{*T} \frac{\alpha(s)}{\Lambda(s)} \sum_{i=1}^N a_{ij} (y_j - y_i) + g_j^* \sum_{i=1}^N a_{ij} (y_j - y_i) \end{aligned} \quad (26)$$

the matching conditions between agents j and i are

$$\begin{aligned} R_i(s)(\Lambda(s) - (\bar{l}_j^{*T} - \bar{l}_{ji}^{*T})\alpha(s)) - k_j Z_i(s)((f_j^{*T} - f_{ji}^{*T})\alpha(s) \\ + (g_j^* - g_{ji}^*)\Lambda(s)) = Z_i(s)R_0(s)\Lambda_0(s) \end{aligned} \quad (27)$$

with

$$c_{ji}^* = \frac{k_i}{k_j}, \quad \bar{l}_{ji}^* = \frac{l_{ji}^*}{c_{ji}^*}, \quad \bar{l}_j^* = \frac{l_j^*}{c_{ji}^*}. \quad (28)$$

Proof. The proof is carried out for agents 1 and 2, without loss of generality. Rewrite (26) to isolate u_2 , as follows

$$\begin{aligned} u_2 = & \frac{(l_{21}^* - l_2^{*T})\alpha u_1 + (f_{21}^* - f_2^{*T})\alpha y_1}{(\Lambda - l_2^{*T}\alpha)} \\ & + \frac{\Lambda(g_{21}^* - g_2^*)y_1 + l_2^*\alpha y_2 + g_2^*y_2\Lambda + c_{21}u_1\Lambda}{(\Lambda - l_2^{*T}\alpha)}. \end{aligned} \quad (29)$$

Substitute (29) into (1) to get

$$\begin{aligned} y_2 = k_2 \frac{Z_2}{R_2} \left[\frac{(l_{21}^* - l_2^{*T})\alpha u_1 + (f_{21}^* - f_2^{*T})\alpha y_1}{(\Lambda - l_2^{*T}\alpha)} \right. \\ \left. + \frac{\Lambda(g_{21}^* - g_2^*)y_1 + l_2^*\alpha y_2 + g_2^*y_2\Lambda + c_{21}u_1\Lambda}{(\Lambda - l_2^{*T}\alpha)} \right] \end{aligned} \quad (30)$$

and rearrange (30) as

$$\begin{aligned} (R_2(s)(\Lambda(s) - l_2^{*T}\alpha(s)) - k_2 Z_2(s)(l_2^{*T}\alpha(s) + \Lambda(s)g_2^*))y_2 \\ - (k_2 Z_2(s)((f_{21}^* - f_2^{*T})\alpha(s) + \Lambda(s)(g_{21}^* - g_2^*)))y_1 \\ = k_2 Z_2(s)(\Lambda(s)c_{21}^* + ((l_{21}^* - l_2^{*T})\alpha(s))u_1. \end{aligned} \quad (31)$$

At the same time, applying (7) to agent 2 leads to

$$\begin{aligned} (Z_2\Lambda_0 R_0)y_2 + k_2 Z_2(f_2^{*T}\alpha + \Lambda g_2^*)y_1 \\ - k_2 Z_2(f_{21}^{*T}\alpha + \Lambda g_{21}^*)y_1 = k_2 Z_2(\Lambda c_{21}^* + ((l_{21}^* - l_2^{*T})\alpha)u_1 \end{aligned} \quad (32)$$

and

$$\begin{aligned} (Z_2(s)\Lambda_0(s)R_0(s))(y_2 - y_1) + (R_2(s)(\Lambda(s) - l_2^{*T}\alpha(s)) \\ - k_2 Z_2(s)(f_{21}^{*T}\alpha(s) + \Lambda(s)g_{21}^*))y_1 \\ = c_{21}^* k_2 Z_2(s)(\Lambda(s) + \frac{l_{21}^{*T}}{c_{21}^*}\alpha(s) - \frac{l_2^{*T}}{c_{21}^*}\alpha(s))u_1. \end{aligned} \quad (33)$$

Let us define $\bar{l}_{21}^* = \frac{l_{21}^{*T}}{c_{21}^*}$ and $\bar{l}_2^* = \frac{l_2^{*T}}{c_{21}^*}$. Using the least common multiplier between (33) and $G_1(s)$, we can rewrite (33) as

$$\begin{aligned} Z_1(Z_2\Lambda_0 R_0)(y_2 - y_1) + Z_1(R_2(\Lambda - l_2^{*T}\alpha) \\ - k_2 Z_2(f_{21}^{*T}\alpha + \Lambda g_{21}^*))y_1 = R_1 Z_2(\Lambda + \bar{l}_{21}^{*T}\alpha - \bar{l}_2^{*T}\alpha)y_1. \end{aligned} \quad (34)$$

The objective now is to cancel everything but the term

$$(Z_1(s)Z_2(s)\Lambda_0(s)R_0(s))(y_2 - y_1) = 0 \quad (35)$$

whose dynamics are stable. In order to achieve this we have

$$\begin{aligned} Z_1(s)(R_2(s)(\Lambda(s) - l_2^{*T}\alpha(s)) \\ - k_2 Z_2(s)(f_{21}^{*T}\alpha(s) + \Lambda(s)g_{21}^*))y_1 \\ = R_1(s)Z_2(s)(\Lambda(s) + \bar{l}_{21}^{*T}\alpha(s) - \bar{l}_2^{*T}\alpha(s))y_1 \\ Z_1(s)(k_2 Z_2(s)(f_2^{*T}\alpha(s) + g_2^*\Lambda(s)) + Z_2(s)R_0(s)\Lambda_0(s)) \\ - k_2 Z_2(s)(f_{21}^{*T}\alpha(s) + \Lambda(s)g_{21}^*))y_1 \\ = R_1(s)Z_2(s)(\Lambda(s) + \bar{l}_{21}^{*T}\alpha(s) - \bar{l}_2^{*T}\alpha(s))y_1. \end{aligned} \quad (36)$$

Now remove the stable $Z_2(s)$ on both sides

$$\begin{aligned} R_1(s)(\Lambda(s) - (\bar{l}_2^* - \bar{l}_{21}^*)^T\alpha(s)) - k_2 Z_1(s)((f_2^{*T} - f_{21}^{*T})\alpha(s) \\ - (g_2^* - g_{21}^*)\Lambda(s)) = Z_1(s)\Lambda_0(s)R_0(s) \end{aligned} \quad (37)$$

which gives the distributed matching condition between neighboring agents 2 and 1. \square

Remark 2. The proof of Proposition 1 reveals the intrinsic meaning of the matching gains in (27), which are the ideal gains allowing agent j to synchronize to agent i , i.e. $y_j \rightarrow y_i$ using neighboring information. Furthermore, after comparing the classical matching conditions (7) with the distributed matching conditions (27), we see that they both have solution under the same Assumptions A1-A4, M1-M2 and E1. That is, no extra assumptions are required for the solvability of (27).

Remark 3. The control (26) depends on $\Lambda(s)$ which includes $Z_0(s)$: this means that some knowledge of the leader dynamics must be available in the network. This is consistent with other popular distributed protocols in literature: in fact, global knowledge of the exosystem dynamics S is generally assumed in cooperative output regulation [14], while global knowledge of the leader dynamics A_0 is used in consensus [30]. The rationale is that, as soon as the leader dynamics are constant, they can be broadcast and made globally known, whereas this cannot be done for the time-varying leader signals.

Note that the matching conditions (27) introduce new gains $l_{ji}^*, f_{ji}^*, g_{ji}^*$ and c_{ji}^* : since these gains (together with l_j^*, f_j^*, g_j^* and c_j^*) are unknown, we propose a new adaptive law. First, let us introduce the controller for agent 2

$$\begin{aligned} a_{12}u_2 = a_{12} \left[l_{21}^T \frac{\alpha(s)}{\Lambda(s)} u_1 + f_{21}^T \frac{\alpha(s)}{\Lambda(s)} y_1 + g_{21}y_1 + c_{21}u_1 \right. \\ \left. + l_2^T \frac{\alpha(s)}{\Lambda(s)} (u_2 - u_1) + f_2^T \frac{\alpha(s)}{\Lambda(s)} (y_2 - y_1) + g_2(y_2 - y_1) \right] \end{aligned} \quad (38)$$

where $l_{21}, l_2, f_{21}, f_2, g_{21}, g_1$, and c_{21} are the estimates for $l_{21}^*, l_2^*, f_{21}^*, f_2^*, g_{21}^*, g_1^*$, and c_{21}^* . A remark and a result follow.

Remark 4. The controller (38) is distributed because it uses information (in particular, both states and inputs) available from neighbors. In fact, if agent 2 were connected to agent 0, it would suffice to take a decentralized model reference adaptive controller in the form

$$a_{02}u_2 = a_{02} \left[l_2^T \frac{\alpha(s)}{\Lambda(s)} u_2 + f_2^T \frac{\alpha(s)}{\Lambda(s)} y_2 + g_2 y_2 + c_2 r \right], \quad (39)$$

which is not-implementable for the lack of r . By comparing (38) with the not-implementable (39) we note that agent 2 uses the signals (states and input) from agent 1 and the extra matching gains between agents 1 and 2 to reconstruct the reference input r . Similar reconstruction mechanisms appear in protocols based on distributed observer [13], [17], where, in place of neighboring inputs, agent 2 would use auxiliary observed signals from agent 1 to reconstruct the exosystem signals.

Result 2. Under Assumptions A1-A4, M1-M2 and E1, the adaptive law

$$\begin{aligned} \dot{\omega}_{u_1} &= F\omega_{u_1} + du_1 & \dot{\omega}_{u_{21}} &= F\omega_{u_{21}} + d(u_2 - u_1) \\ \dot{\omega}_{y_1} &= F\omega_{y_1} + dy_1 & \dot{\omega}_{y_{21}} &= F\omega_{y_{21}} + d(y_2 - y_1) \\ a_{12}u_2 &= \theta_2^T \omega_2 \\ \dot{\theta}_2 &= -\Gamma a_{12}e_{21}\omega_2 \text{sgn}\left(\frac{k_2}{k_0}\right) \end{aligned} \quad (40)$$

where $e_{21} = y_2 - y_1$, F and d as in (10), $\Gamma > 0$, and

$$\begin{aligned} \omega_2 &= a_{12} \begin{bmatrix} \omega_{u_1}^T & \omega_{y_1}^T & y_1 & u_1 & \omega_{u_{21}}^T & \omega_{y_{21}}^T & y_2 - y_1 \end{bmatrix}^T, \\ \theta_2 &= [l_{21}^T \ f_{21}^T \ g_{21} \ c_{21} \ l_2^T \ f_2^T \ g_2]^T \end{aligned} \quad (41)$$

achieves $y_2 \rightarrow y_1$ for $t \rightarrow \infty$.

Proof. To derive the adaptation law (40) of agent 2 we define

$$\dot{\omega}_{u_2} = F\omega_{u_2} + du_2 \quad \dot{\omega}_{y_2} = F\omega_{y_2} + dy_2. \quad (42)$$

Then, augmenting the state of agent 2 with the states (42), $\bar{x}_2 = [x_2^T \ \omega_{u_2}^T \ \omega_{y_2}^T]^T$ allows us to write

$$\begin{aligned} \dot{\bar{x}}_2 &= \begin{bmatrix} A_2 & 0 & 0 \\ 0 & F & 0 \\ dh_2^T & 0 & F \end{bmatrix} \bar{x}_2 + \begin{bmatrix} b_2 \\ d \\ 0 \end{bmatrix} u_2 \\ y_2 &= [h_2^T \ 0 \ 0] \bar{x}_2 \end{aligned} \quad (43)$$

where (A_2, B_2, h_2) is a state-space realization of agent 2. The use of the matching conditions (37) between agent 2 and agent 1 on the terms under the parentheses here

$$\begin{aligned} \bar{\dot{x}}_1 &= \bar{A}_1 \bar{x}_1 + \bar{B}_1 u_1 & \bar{\dot{x}}_2 &= \bar{A}_2 \bar{x}_2 + \bar{B}_2 \theta_2^* \bar{\omega}_2 + \bar{B}_2 \tilde{\theta}_2^T \bar{\omega}_2 \\ y_1 &= \bar{C}_1^T \bar{x}_1 & y_2 &= \bar{C}_2^T \bar{x}_2 \end{aligned} \quad (44)$$

with $\bar{\omega}_2 = \omega_2/a_{12}$ and

$$\bar{A}_2 = \begin{bmatrix} A_2 + b_2 g_2^* h_2^T & b_2 l_2^{*T} & b_2 f_2^{*T} \\ dg_2^* h_2^T & F + dl_2^{*T} & df_2^{*T} \\ -dh_2^T & 0 & F \end{bmatrix} \quad (45)$$

$$\bar{B}_2 = \begin{bmatrix} b_2 \\ d \\ 0 \end{bmatrix}, \quad \bar{C}_2^T = [h_2^T \ 0 \ 0] \quad (46)$$

gives rise to the following dynamics of $\tilde{x}_{21} = \bar{x}_2 - \bar{x}_1$

$$\begin{aligned} \dot{\tilde{x}}_{21} &= \bar{A}_2 \tilde{x}_{21} + \bar{B}_2 \rho_2^* \tilde{\theta}_2^T \bar{\omega}_2 \\ e_{21} &= \bar{C}_2^T \tilde{x}_{21} \end{aligned} \quad (47)$$

where $\bar{B}_2 = \bar{B}_2 c_2^*$, $\rho_2^* = \frac{1}{c_2^*}$, and $\tilde{\theta}_2 = \theta_2 - \theta_2^*$. In addition, it can be verified that

$$\bar{C}_2(sI - \bar{A}_2)^{-1} \bar{B}_2 = G_0(s). \quad (48)$$

In line with (19) and (21), we take the Lyapunov function

$$V_{21}(\tilde{\theta}_2, \tilde{x}_{21}) = a_{12}^2 \frac{\tilde{x}_{21}^T P \tilde{x}_{21}}{2} + \frac{\tilde{\theta}_2^T \Gamma^{-1} \tilde{\theta}_2}{2} |\rho_2^*| \quad (49)$$

with $P = P^T > 0$ satisfying the Kalman-Yakubovich Lemma

$$\begin{aligned} P\bar{A}_2 + \bar{A}_2^T P &= -qq^T - \nu L \\ P\bar{B}_2 &= \bar{C}_2. \end{aligned} \quad (50)$$

The time derivative of V_{21} is given by

$$\begin{aligned} \dot{V}_{21} &= -a_{12}^2 \frac{\tilde{x}_{21}^T qq^T \tilde{x}_{21}}{2} - a_{12}^2 \frac{\nu}{2} \tilde{x}_{21}^T L \tilde{x}_{21} \\ &\quad + a_{12} \tilde{x}_{21}^T P \bar{B}_2 \rho_2^* \tilde{\theta}_2^T \omega_2 + \tilde{\theta}_2^T \Gamma^{-1} \dot{\tilde{\theta}}_2 |\rho_2^*|. \end{aligned} \quad (51)$$

Since $\tilde{x}_{21}^T P \bar{B}_2 = \tilde{x}_{21}^T \bar{C}_2 = e_{21}$ and $\rho_2^* = |\rho_2^*| \text{sgn}(\rho_2^*)$, we can delete the last two terms by choosing

$$\dot{\tilde{\theta}}_2 = \dot{\theta}_2 = -\Gamma a_{12} e_{21} \omega_2 \text{sgn}(\rho_2^*) \quad (52)$$

which leads to

$$\dot{V}_{21} = -a_{12}^2 \frac{\tilde{x}_{21}^T qq^T \tilde{x}_{21}}{2} - a_{12}^2 \frac{\nu}{2} \tilde{x}_{21}^T L \tilde{x}_{21}. \quad (53)$$

From (53) we obtain that V_{21} has a finite limit, and therefore $\tilde{x}_{21}, \tilde{\theta}_2 \in \mathcal{L}_\infty$. Because $\tilde{x}_{21} = \bar{x}_2 - \bar{x}_1 \in \mathcal{L}_\infty$ and $\bar{x}_1 \in \mathcal{L}_\infty$, we have $\bar{x}_2 \in \mathcal{L}_\infty$, which implies $x_2, y_2, \omega_{u_{21}}, \omega_{u_2}, \omega_{y_{21}}, \omega_{y_2} \in \mathcal{L}_\infty$. Since from (53) we can establish that \dot{V}_1 has bounded integral, we have $\tilde{x}_{21}, e_{21} \in \mathcal{L}_2$. Furthermore using $\theta_2, \omega_2, \tilde{x}_{21} \in \mathcal{L}_\infty$ in (47) we have $e_{21}, \dot{e}_{21} \in \mathcal{L}_\infty$. From Barbalat's Lemma, this implies $e_{21} \rightarrow 0$ for $t \rightarrow \infty$, which concludes the proof. \square

V. ADAPTIVE OUTPUT SYNCHRONIZATION

To arrive at the main result, the last step is to deal with the case of a follower (let us call it agent 3) aiming at synchronizing to two parent neighbors (let us call them agents 1 and 2). With a directed connection from 1 to 3 and from 2 to 3, the digraph is described by $\mathcal{N} = \{1, 2, 3\}$, $\mathcal{E} = \{(1, 3), (2, 3)\}$. In order to synchronize agent 3 to agent 1 and 2, we need to define a controller: motivated by (26), we propose

$$\begin{aligned} (a_{13} + a_{23})u_3 &= a_{13} l_{31}^T \frac{\alpha(s)}{\Lambda(s)} u_1 + a_{13} f_{31}^T \frac{\alpha(s)}{\Lambda(s)} y_1 + a_{13} g_{31} y_1 \\ &\quad + a_{13} c_{31} u_1 + a_{23} l_{32}^T \frac{\alpha(s)}{\Lambda(s)} u_2 + a_{23} f_{32}^T \frac{\alpha(s)}{\Lambda(s)} y_2 + a_{23} g_{32} y_2 \\ &\quad + a_{23} c_{32} u_2 + l_3^T \frac{\alpha(s)}{\Lambda(s)} u_{a3} + f_3^T \frac{\alpha(s)}{\Lambda(s)} e_{a3} + g_3 e_{a3} \end{aligned} \quad (54)$$

where $u_{a3} = a_{13}(u_3 - u_1) + a_{23}(u_3 - u_2)$, $e_{a3} = a_{13}e_{31} + a_{23}e_{32}$ and $e_{31} = y_3 - y_1$, $e_{32} = y_3 - y_2$; moreover, all the control gains $l_{31}, f_{31}, g_{31}, c_{31}, l_{32}, f_{32}, g_{32}, c_{32}, l_3, f_3, g_3$ are appropriate

estimates of ideal gains coming from the matching conditions (7) and (27). The following result holds.

Result 3. Under Assumptions A1-A4, M1-M2 and E1, the adaptive law

$$\begin{aligned} \dot{\omega}_{u_1} &= F\omega_{u_1} + du_1 & \dot{\omega}_{y_1} &= F\omega_{y_1} + dy_1 \\ \dot{\omega}_{u_2} &= F\omega_{u_2} + du_2 & \dot{\omega}_{y_2} &= F\omega_{y_2} + dy_2 \\ \dot{\omega}_{u_{a_3}} &= F\omega_{u_{a_3}} + du_{a_3} & \dot{\omega}_{e_{a_3}} &= F\omega_{e_{a_3}} + de_{a_3} \\ (a_{13} + a_{23})u_3 &= \theta_3^T \omega_3 & \dot{\theta}_3 &= -\Gamma e_{a_3} \omega_3 \text{sgn}\left(\frac{k_3}{k_0}\right) \end{aligned} \quad (55)$$

where F and d are as in (10), $\Gamma > 0$, and

$$\begin{aligned} \omega_3 &= [a_{13}\omega_{u_1}^T \ a_{13}\omega_{y_1}^T \ a_{13}y_1 \ a_{13}u_1 \ a_{23}\omega_{u_2}^T \ a_{23}\omega_{y_2}^T \\ &\quad a_{23}y_2 \ a_{23}u_2 \ \omega_{u_{a_3}}^T \ \omega_{e_{a_3}}^T \ e_{a_3}]^T, \\ \theta_3 &= [l_{31}^T \ f_{31}^T \ g_{31} \ c_{31} \ l_{32}^T \ f_{32}^T \ g_{32} \ c_{32} \ l_3^T \ f_3^T \ g_3]^T \end{aligned} \quad (56)$$

achieves $y_3 \rightarrow (a_{13}y_1 + a_{23}y_2)/(a_{13} + a_{23})$ for $t \rightarrow \infty$.

Proof. As compared with ω_1 in (10) and ω_2 in (41), ω_3 in (56) has two types of weights, a_{13} and a_{23} , in view of the connection with two agents. Now, to derive the adaptation law (55) of agent 3 we have to define the dynamics of the errors e_{31} and e_{32} . Using similar steps as (44)-(46) we find

$$\begin{aligned} \dot{\tilde{x}}_{31} &= \bar{A}_3 \tilde{x}_{31} + \bar{B}_3 \tilde{\theta}_{31}^T \bar{\omega}_{31} & \dot{\tilde{x}}_{32} &= \bar{A}_3 \tilde{x}_{32} + \bar{B}_3 \tilde{\theta}_{32}^T \bar{\omega}_{32} \\ e_{31} &= \bar{C}_3^T \tilde{x}_{31} & e_{32} &= \bar{C}_3^T \tilde{x}_{32} \end{aligned} \quad (57)$$

where $\bar{\omega}_{31} = \omega_{31}/a_{13}$, $\bar{\omega}_{32} = \omega_{32}/a_{23}$ and

$$\begin{aligned} \omega_{31} &= a_{13} [\omega_{u_1}^T \ \omega_{y_1}^T \ y_1 \ u_1 \ \omega_{u_{31}}^T \ \omega_{e_{31}}^T \ (y_3 - y_1)]^T, \\ \omega_{32} &= a_{23} [\omega_{u_2}^T \ \omega_{y_2}^T \ y_2 \ u_2 \ \omega_{u_{32}}^T \ \omega_{e_{32}}^T \ (y_3 - y_2)]^T, \\ \tilde{\theta}_{31} &= [\tilde{l}_{31}^T \ \tilde{f}_{31}^T \ \tilde{g}_{31} \ \tilde{c}_{31} \ \tilde{l}_3^T \ \tilde{f}_3^T \ \tilde{g}_3]^T, \\ \tilde{\theta}_{32} &= [\tilde{l}_{32}^T \ \tilde{f}_{32}^T \ \tilde{g}_{32} \ \tilde{c}_{32} \ \tilde{l}_3^T \ \tilde{f}_3^T \ \tilde{g}_3]^T \end{aligned} \quad (58)$$

and $\omega_{u_{31}}$ and $\omega_{u_{32}}$ are the filtered versions of $(u_3 - u_1)$ and $(u_3 - u_2)$, respectively. This motivates the Lyapunov function

$$V_{321}(\tilde{\theta}_2, \tilde{x}_{21}) = \frac{\tilde{x}_{a_3}^T P \tilde{x}_{a_3}}{2} + \frac{\tilde{\theta}_3^T \Gamma^{-1} \tilde{\theta}_3}{2} |\rho_3^*| \quad (59)$$

where $\tilde{x}_{a_3} = a_{13}\tilde{x}_{31} + a_{23}\tilde{x}_{32}$. The time derivative becomes, through (55)

$$\begin{aligned} \dot{V}_{321} &= -\frac{\tilde{x}_{a_3}^T q q^T \tilde{x}_{a_3}}{2} - \frac{\nu}{2} \tilde{x}_{a_3}^T L \tilde{x}_{a_3} \\ &\quad + \tilde{x}_{a_3}^T P \bar{B}_3 \rho_3^* \tilde{\theta}_3^T \omega_3 + \tilde{\theta}_3^T \Gamma^{-1} \dot{\tilde{\theta}}_3 |\rho_3^*| \\ &= -\frac{\tilde{x}_{a_3}^T q q^T \tilde{x}_{a_3}}{2} - \frac{\nu}{2} \tilde{x}_{a_3}^T L \tilde{x}_{a_3} \end{aligned} \quad (60)$$

where the Kalman-Yakovich lemma analogous to (50) has led to $\tilde{x}_{a_3}^T P \bar{B}_3 = \tilde{x}_{a_3}^T \bar{C}_3 = e_{a_3}$. Using the usual Lyapunov arguments as in Result 2 we prove $\tilde{x}_{a_3} \rightarrow 0$ and consequently $e_{a_3} \rightarrow 0$. This concludes the proof. \square

Remark 5. From Results 1 and 2, using the Lyapunov function $V_1 + V_{21}$ we conclude synchronization of both agents 1 and 2 to the reference model. Furthermore, it is not difficult to conclude synchronization also when agent 1 has multiple followers.

Fig. 1: Summary of Results 1, 2 and 3.

Similarly, Result 2 can be applied to any network with a directed tree topology in which each leaf has one parent and the root node has access to the reference signal r . In addition, by combining Results 1, 2 and 3 via the Lyapunov function $V_1 + V_{21} + V_{321}$, we have that the outputs of agents 1 and 2 converge to y_m , and consequently the output of agent 3 will converge to the average of the outputs of agents 1 and 2, i.e. to y_m as well. This situation is summarized in Fig. 1. This reasoning is the building block to achieve synchronization over general acyclic graphs, as explained in the following.

A. General acyclic case

Consider a set of N agents with transfer function

$$y_i = G_i(s)u_i = k_i \frac{Z_i(s)}{R_i(s)} u_i, \quad i \in \{1, \dots, N\} \quad (61)$$

and satisfying Assumptions A1-A4. Consequently, all the matching conditions defined by (7) and (27) hold. These conditions allow us to achieve synchronization by ‘cancelling’ heterogeneity via appropriate gains. We make the following assumption on the communication topology.

Network assumption:

N1. The directed communication graph is acyclic and contains a directed spanning tree with the leader as the root node.

Remark 6. The absence of cycles implies the existence of a vertex permutation such that the adjacency matrix has upper triangular form. This assumption is common in protocols based on distributed input [19], [22], [39]. Extensions to cyclic and undirected networks will be discussed in Sect. V-B.

In order to synchronize all agents, we propose for the agents connected to the reference model the controller inspired by (3)

$$a_{0j}u_j = a_{0j} \left[l_j^T \frac{\alpha(s)}{\Lambda(s)} u_j + f_j^T \frac{\alpha(s)}{\Lambda(s)} y_j + g_j y_j + c_j r \right] \quad (62)$$

and for the agents not connected to the reference model the controller inspired by (26)

$$\begin{aligned} \sum_{i=1}^N a_{ij}u_j &= \sum_{i=1}^N a_{ij}l_{ji}^T \frac{\alpha(s)}{\Lambda(s)} u_i + \sum_{i=1}^N a_{ij}f_{ji}^T \frac{\alpha(s)}{\Lambda(s)} y_i + \sum_{i=0}^N a_{ij}g_{ji}y_i \\ &\quad + \sum_{i=1}^N a_{ij}c_{ji}u_i + l_j^T \frac{\alpha(s)}{\Lambda(s)} \sum_{i=1}^N a_{ij}(u_j - u_i) \\ &\quad + f_j^T \frac{\alpha(s)}{\Lambda(s)} \sum_{i=1}^N a_{ij}(y_j - y_i) + g_j \sum_{i=1}^N a_{ij}(y_j - y_i) \end{aligned} \quad (63)$$

where all the control gains l_{ji} , f_{ji} , g_{ji} , c_{ji} , l_j , f_j , g_j are appropriate estimates of ideal gains coming from the matching conditions (7) and (27). The following result holds.

Result 4. Under Assumptions A1-A4, M1-M2, E1 and N1, the adaptive law as in Result 1 for the agents connected to the reference model, and for the other agents the adaptive law

$$\begin{aligned}\dot{\omega}_{u_{aj}} &= F\omega_{u_{aj}} + d \sum_{i=1}^N a_{ij}(u_j - u_i) & \dot{\omega}_{u_k} &= F\omega_{u_k} + du_k \\ \dot{\omega}_{e_{aj}} &= F\omega_{e_{aj}} + d \sum_{i=1}^N a_{ij}(y_j - y_i) & \dot{\omega}_{y_k} &= F\omega_{y_k} + dy_k \\ \sum_{i=1}^N a_{ij}u_j &= \theta_j^T \omega_j & \dot{\theta}_j &= -\Gamma \sum_{i=1}^N a_{ij}(y_j - y_i) \omega_j \text{sgn}\left(\frac{k_j}{k_0}\right)\end{aligned} \quad (64)$$

where $k : a_{kj} \neq 0$, F and d are as in (10), $\Gamma > 0$ and

$$\begin{aligned}\omega_j &= [a_{kj}\omega_{u_k}^T \quad a_{kj}\omega_{y_k}^T \quad a_{kj}y_k \quad a_{kj}u_k \quad \dots \quad k \in \{1, \dots, N\} \\ &\quad \dots \quad \omega_{u_{aj}}^T \quad \omega_{e_{aj}}^T \quad \sum_{i=0}^N a_{ij}(y_j - y_i)]^T, \\ \theta_j &= [l_{jk}^T \quad f_{jk}^T \quad g_{jk} \quad c_{jk} \quad \dots \quad k \in \{1, \dots, N\} \\ &\quad \dots \quad l_j^T \quad f_j^T \quad g_j]^T\end{aligned} \quad (65)$$

achieves $y_i \rightarrow y_m$, $i \in \{1, \dots, N\}$.

Proof. The derivation of the adaptation law (64) of agent j follows similar steps as in Result 3, through the error dynamics

$$\begin{aligned}\dot{\tilde{x}}_{ji} &= \bar{A}_j \tilde{x}_{ji} + \bar{B}_j \tilde{\theta}_{ji}^T \omega_{ji} \\ e_{ji} &= \bar{C}_j^T \tilde{x}_{ji}\end{aligned} \quad (66)$$

where $\tilde{\theta}_{ji}$ contains some of the components of $\tilde{\theta}_j$, and ω_{ji} contains some of the components of ω_j . This motivates the following Lyapunov function

$$V(\tilde{\theta}, \tilde{x}) = \sum_{j=1}^N \frac{\tilde{x}_{aj}^T P \tilde{x}_{aj}}{2} + \sum_{j=1}^N \frac{\tilde{\theta}_j^T \Gamma^{-1} \tilde{\theta}_j}{2} |\rho_j^*| \quad (67)$$

where $\tilde{x}_{aj} = \sum_{i=0}^N a_{ij} \tilde{x}_{ji}$: the time derivative gives, through (64)

$$\dot{V} = -\sum_{j=1}^N \frac{\tilde{x}_{aj}^T q q^T \tilde{x}_{aj}}{2} - \frac{\nu}{2} \sum_{j=1}^N \tilde{x}_{aj}^T L \tilde{x}_{aj}. \quad (68)$$

Using Lyapunov arguments we prove $\tilde{x}_{aj} \rightarrow 0$ and using N1 we have $\tilde{x}_{ji} \rightarrow 0$ and $e_{ji} \rightarrow 0$. This concludes the proof. \square

Remark 7. The adaptive laws analyzed in this work are based on agents free of observation noise and unmodeled dynamics. In the presence of such phenomena, the proposed adaptive laws (64) should be replaced with robust adaptive laws in line with [38, Chap. 8]. For state synchronization, it has been shown that robust adaptive laws employing leakage, parameter projection or dynamic normalization attain robustness to bounded noises by achieving a bounded synchronization error, whose bound depends on the size of the noise [40]. In addition, it has been shown that these techniques can cope with unmodeled dynamics in the form of communication delays [41]. Similar good properties hold true for the output synchronization design proposed in this paper, but space limitations prevent us from presenting them at length.

B. Handling cyclic and undirected graphs

While the parameterization (66) is valid for acyclic graphs, it is of interest to investigate under which conditions it can be extended to graphs beyond Assumption N1, e.g. cyclic and undirected graphs. It is clear that, in the presence of cycles and undirected links, the computation of the derivative of a candidate Lyapunov function requires to sum dynamics with state-space realization $(\bar{A}_j, \bar{B}_j, \bar{C}_j^T)$ with other dynamics with a possibly different state-space realization $(\bar{A}_k, \bar{B}_k, \bar{C}_k^T)$. A common state-space realization is a sufficient condition for making such summation possible: in adaptive literature, common state-space realizations have been shown to exist for state synchronization of systems with matched uncertainties [40], and for output synchronization using state-feedback of systems with homogeneous uncertain numerator [37, Sect. 4.2]. For output synchronization using output-feedback as in this work, a common realization of (66), call it $(\bar{A}_0, \bar{B}_0, \bar{C}_0^T)$, requires all agents to have homogeneous uncertain numerator and denominator, with possibly heterogeneous uncertain high-frequency gains [38, Sect. 6.3]. Under this condition, it is possible to show that the following holds

$$\dot{\tilde{x}}_a = (I_N \otimes \bar{A}_0) \tilde{x}_a + \text{diag}(\bar{B}_0 \tilde{\theta}_1^T \omega_1, \dots, \bar{B}_0 \tilde{\theta}_N^T \omega_N) \quad (69)$$

with $\tilde{x}_a = [\tilde{x}_{a1} \dots \tilde{x}_{aN}]^T$, even in the presence of cyclic and undirected connections. At this point, the Lyapunov function

$$V(\tilde{\theta}, \tilde{x}) = \tilde{x}_a^T (I \otimes \frac{P}{2}) \tilde{x}_a + \sum_{j=1}^N \frac{\tilde{\theta}_j^T \Gamma^{-1} \tilde{\theta}_j}{2} |\rho_j^*| \quad (70)$$

can potentially be adopted for cyclic and undirected graphs. However, in distributed input protocols, it is also necessary to guarantee that the input u_j is well defined for all time instants: this might not be true on general graphs [39]. To explain this point, let us collect all inputs in (63) on the left-hand side, leading to $U[u_1 \dots u_N]^T = [\beta_1 \dots \beta_N]^T$ for an appropriate square matrix U . Assumption N1 guarantees that U is always invertible: in fact, after ordering the agents in such a way that U is upper triangular, we have $\det(U) > 0$ and the control input u_j always well defined. When assumption N1 is violated, since U depends on the estimates c_{ji} , it is difficult if at all possible to guarantee invertibility of U for every estimate. Despite this difficult analytic aspect, the simulations in the next section show that the same algorithm in Result 4 can handle networks beyond Assumption N1, with some heterogeneity in the denominator/numerator, and that U turns out to be invertible at all time instants.

VI. SIMULATIONS

Simulations are performed to illustrate the effectiveness of the approach. The simulations are carried out on the directed graph shown in Fig. 2, where the reference model is indicated as agent 0. The agents are second-order with transfer function

$$G_i(s) = \frac{s+b}{s^2 - a_2 s - a_1} \quad (71)$$

Fig. 2: The leader-follower directed communication graph.

Fig. 3: Acyclic graph: input/output responses of reference model (dash-dotted) and all agents (solid).

which corresponds to the observable canonical form

$$\begin{aligned} \dot{x}_i &= \begin{bmatrix} 0 & a_1 \\ 1 & a_2 \end{bmatrix} x_i + \begin{bmatrix} b \\ 1 \end{bmatrix} u_i \\ y &= \begin{bmatrix} 0 & 1 \end{bmatrix} x_i. \end{aligned} \quad (72)$$

The specific heterogeneous coefficients and initial conditions of each agent are reported in Table I. Except for the reference model, which is asymptotically stable, all agents are open-loop unstable: in addition, all numerators are Hurwitz as per assumption. The relative degree is $n^* = 1$ and the upper bound to the degree of the denominator is taken $n = 2$. Note that the numerical values in Table I are used only to simulate the agents, while the synchronization protocol does not use the knowledge of the agents' coefficients, except $\text{sgn}(k_i) = 1$, $\forall i$. The other design parameters are taken as $\Lambda(s) = s + 1$ and the adaptive gain Γ_i is a diagonal matrix with gains $\gamma_l = 1$, $\gamma_f = 3$, $\gamma_g = 10$, and $\gamma_c = 1$, which correspond to the gains multiplying the coefficients l , f , g and c , respectively. Note that dimension of Γ_i depends on the dimension of ω_i : $\dim(\omega_1) = 4$, $\dim(\omega_2) = \dim(\omega_3) = \dim(\omega_5) = \dim(\omega_6) = 7$, and $\dim(\omega_4) = 11$ (because agent 4 has 2 parents). All coupling gains are initialized to be 0.

	a_1	a_2	b	x_0
agent #0	-0.5	-1	1	$[1 \ -1]'$
agent #1	-1	2	1	$[1 \ 1]'$
agent #2	-0.75	2.5	0.5	$[-1 \ -1]'$
agent #3	-1.25	2	1.25	$[-1 \ 0]'$
agent #4	-0.5	1	0.75	$[0 \ 1]'$
agent #5	-0.75	1	1.5	$[1 \ 0]'$
agent #6	-1.5	2.5	1	$[-1 \ 1]'$

TABLE I: Coefficients and initial conditions of the agents.

Fig. 4: Acyclic graph: Estimated (solid) vs ideal (dashed) gains.

Fig. 5: Acyclic graph: Output synchronization errors $y_i - y_0$ for all agents.

The resulting synchronization for a sinusoidal reference signal is shown in Fig. 3: the outputs converge to the same behavior, while the inputs differ in view of heterogeneity. The output synchronization error can be seen in Fig. 5. Some of the estimated gains of the controllers (as compared to the ideal gains coming from the matching conditions) are shown in Fig. 4: it is noticed that not necessarily the estimated gains will converge to the ideal gains. This is a well known result in adaptive control [37]: only a persistently exciting input of sufficiently large order (not guaranteed by a single sinusoid) will lead to convergence to the ideal gains.

Fig. 6: Cyclic communication graph.

In order to investigate relaxations to Assumption N1, we perform additional simulations on the graph in Fig. 6, which

Fig. 7: Cyclic graph: Output/input responses of reference model (dash-dotted) and all agents (solid).

Fig. 9: Cyclic graph: Output synchronization errors $y_i - y_0$ for all agents.

Fig. 8: Acyclic graph: Estimated (solid) vs ideal (dashed) gains.

presents two cycles among agents (cycle 2-3-4 and cycle 4-5-6). The resulting synchronization for a sinusoidal reference signal is shown in Fig. 7: we can see that also in this cyclic case, the outputs converge to a synchronous solution. The output synchronization error can be seen in Fig. 9. This shows that in practice the proposed algorithm can handle networks beyond Assumption N1. Some of the estimated gains of the controllers (as compared to the ideal gains coming from the matching conditions) are shown in Fig. 8: not necessarily the estimated gains will converge to the ideal gains or to the same values as in the acyclic case.

VII. CONCLUSION

This work proposed a methodology for output synchronization of heterogeneous agents with linear and unknown dynamics. A distributed model reference adaptive control formulation was used to solve the problem. Synchronization implies matching a common behavior, and for the problem at hand, we have defined two types of matching conditions: the matching conditions between an agent and the reference model, and the matching conditions among neighboring agents. Solvability of the first set of matching conditions implies

solvability of the second set as well. Since all the matching gains are unknown (in view of the unknown dynamics), all the gains are adaptive and estimated using a Lyapunov-based approach.

Several research directions can stem from this work: first, since we have shown that the matching gains include both feedback and coupling gains, it is worth investigating the use of the evolution of each coupling gain to restructure the topology of the network [42]. Another related topic is the study of switching topologies via adaptive switching tools [43].

Simone Baldi (M'16) received the B.Sc., M.Sc. and Ph.D. degree from University of Florence, Italy, in 2005, 2007, and 2011 respectively. He is currently Assistant Professor at the Delft Center for Systems and Control, Delft University of Technology. Previously, he held post-doc researcher positions at University of Cyprus, and at Information Technologies Institute, CERTH, Thessaloniki. His research interests include adaptive and switched systems with applications in networked control and multi-agent systems.

Shuai Yuan received the B.Sc. and M.Sc. degree in Mechanical Science and Engineering from Harbin Institute of Technology, Huazhong University of Science and Technology, China, in 2011 and 2014 respectively. He is currently a PhD candidate at the Delft Center for Systems and Control, Delft University of Technology. His research interests include adaptive systems and switched systems.

Paolo Frasca (M'13) received the Ph.D. degree in Mathematics for Engineering Sciences from Politecnico di Torino, Torino, Italy, in 2009. Between 2008 and 2013, he held research and visiting positions at the University of California, Santa Barbara (USA), at the IAC-CNR (Rome, Italy), at the University of Salerno (Italy), and at the Politecnico di Torino. From 2013 to 2016, he was an Assistant Professor at the University of Twente in Enschede, the Netherlands. In October 2016 he joined the CNRS as a Researcher: he is currently affiliated with GIPSA-lab in Grenoble, France. His research interests are in the theory of network systems and cyber-physical systems, with applications to robotic, sensor, infrastructural, and social networks. He is a recipient of the 2013 SIAG/CST Best SICON Paper Prize. Dr. Frasca has served in the Conference Editorial Boards of several events, including IEEE CDC, ACC, ECC, MTNS, IFAC NecSys, and is currently serving as Associate Editor for the *International Journal of Robust and Nonlinear Control*, the *Asian Journal of Control*, and the *IEEE Control Systems Letters*.
